# Life-table Representations of Family Dynamics in the 21 ${ }^{\text {st }}$ Century 

Gunnar Andersson, Elizabeth Thomson, and Aija Duntava
Stockholm University Demography Unit, 10691 Stockholm, Sweden

## BACKGROUND

A key resource for cross-national comparative research on family dynamics (Andersson and Philipov 2002) is seriously outdated.

## OBJECTIVE AND METHODS

We provide an update of the life-table estimates by Andersson and Philipov (2002) based on data from the Generations and Gender Surveys and other related surveys in 18 countries across Europe and the USA.

## RESULTS

Life-table estimates of family formation of women and men, union dynamics, and children's experience of family disruption and family formation demonstrate the degree of variation in family dynamics across countries.

## CONCLUSIONS

Our descriptive findings provide the basis for more in-depth research on the causes and consequences of differences in family dynamics across contexts.

## CONTRIBUTION

The Appendix Tables of the current manuscript is a new resource for comparative research on family dynamics in the early $21^{\text {st }}$ century.

## INTRODUCTION

"Any sound investigation of a demographic phenomenon must originate from some knowledge about its very basic patterns: how common the demographic event of interest is, at what ages it typically occurs, and how such patterns in a country differ from those in other countries and periods" (Andersson and Philipov 2002).

The above assertion was the rationale for a key resource for cross-national comparative research on family dynamics in the 1980s and 1990s. Andersson and Philipov (2002) generated a standard set of life-tables and other descriptive measures for family formation and family dissolution, focusing in particular on the role of cohabitation and parenthood; see also Andersson (2002a, 2002b). They used data from the Fertility and Family Surveys that were conducted in a large number of European countries in 1989-1997, and comparable data from the US National Survey of Family Growth. Appropriate data were available for 16 countries: Sweden, Norway, Finland, France, the USA, Austria, Germany, Belgium, Italy, Spain, the Czech Republic, Hungary, Slovenia, Latvia, Lithuania, and Poland. For Belgium the data covered only Flanders; East and West Germany were treated as separate countries as the retrospective biographical events occurred mostly prior to reunification.

These data are now seriously out of date. Fortunately, the Generations and Gender Surveys and other related country-specific surveys have since then provided updated data on birth and union histories. Many of these histories have been compiled in a single file known as the Harmonized Histories (http://www.nonmarital.org/HarmHist.htm). Additional and related data are available from the Changing Life Course Regimes (CLiCR) database (Duntava \& Billingsley
2013). In our current project, we have generated the same estimates as reported by Andersson and Philipov (2002) from these new histories for the period around 2005. Estimates cover 19 countries: Sweden, Norway, Germany, France, USA, Spain, Italy, Austria, Netherlands, Belgium, Estonia, Lithuania, Poland, the Czech Republic, Hungary, the Russian Federation, Romania, Bulgaria, and Georgia. Direct comparisons can be made for 11 countries included in the previous report.

For each of the 19 countries listed above, we completely replicated analyses and present tables in the same form as in Andersson and Philipov. Life tables are constructed for synthetic cohorts, based on transition probabilities calculated from reported events and exposures to events during the 72 months prior to each interview. The estimates thus tell us what demographic patterns would arise if the calculated age-specific transition probabilities prevail during a generation or so.

Three broad groups of tabulations are included. First we present measures of women's and men's family formation, i.e., the cumulative percent of women or men who would experience a specific demographic event by single-year ages from 15 to 50 . As compared to Andersson and Philipov and to cover patterns in postponed family formation, we have extended the upper age limit with another ten years of observation (in some cases we still have to stop observation at earlier ages due to age limits in the survey). Second, we present measures of union experience by duration of union, from union formation to 15 years later. In this case, the union is the unit of observation so information about women and men is pooled. Third, we present life-table measures of children's experience of family formation and of family dissolution, all calculated from information provided by mothers. In most cases, we present information by single years
of age, up to the $15^{\text {th }}$ birthday. Finally, we present a summary of the fractions of total time that men, women, and children would spend in various family types if the observed age-specific spells by family type prevailed throughout the reproductive ages or during childhood.

## DATA QUALITY

The life-table estimates are based on union and birth histories, dated by month and year of event. For co-residential unions we require the start and end date (or month of interview if union has not ended), as well as the marriage date if the couple married at the start or after a period of non-marital cohabitation. Such histories are the foundation of the Generations and Gender Programme, within which the first survey waves were conducted between 2003 and 2013 in 18 countries (Vikat et al., 2008; Vergauwen et al., 2015; Fokkema et al. 2016; www.ggp-i.org). These data have been combined with data from other surveys in the Harmonized Histories (Perelli-Harris et al. 2010; www.nonmarital.org) and the Changing Life-Course Regimes (CLiCR) data base (Duntava and Billingsley 2013), with some eastern and central European countries included in both.

Because these data are all publicly available, we explain below some modifications in the data we used for the life-table analysis. We applied a modified version of the Harmonized Histories code to GGP wave 1 files downloaded from the official website (www.ggp-i.org). For example, missing months in the Harmonized Histories are randomly imputed across the year in which the event occurred; we limited the frame for random assignment to months that followed or preceded events occurring in the same year. We also corrected an error in the Harmonized History code that had placed
all unions for which the start year was missing to occur after other unions; this correction has been made in current versions of the Harmonized Histories as well. The GGP file for Hungary available at the time was discovered to contain large errors, so we produced a corrected data file from data provided by the HCSO Demographic Research Institute of Hungary. The files we created for Bulgaria, Estonia, Hungary, Poland, Romania, and Russia are derived from the CLiCR dataset. Data for the Czech Republic are also found in CLiCR and were harmonized during the work with the current project; at the time CLiCR was created, the Czech GGP data were not yet available. We did not use the HH data from the British Household Panel Survey or the Swiss Household Panel Survey because they did not provide data for all of the transitions or age ranges to be documented. Data for Germany were produced with unique code from the German National Educational Panel Study (Blossfeld et al. 2011) instead of the GGS. The German GGS histories, included in the Harmonized Histories, are known to generate invalid estimates of several birth and union transitions (Kreyenfeld et al. 2013). Because all data were not available in the NEPS, we used the German GGS to derive estimates of home-leaving.

Table A lists the size of study populations for our life-table estimates and ages of respondents to the surveys used in our analysis. Note that there are no data on men in the surveys of Italy and Spain and that we have not used data on any respondents older than 55 years. For all countries, analyses of children's life events are based on those of their mothers. Our retrospective life-table estimates for Austria and the U.S. stop at age 40, as the maximum age in those surveys is just 45 years. In order to capture sufficient observations at our starting age of 15 years, we had to extend the observation window in Germany to nine rather than six years. In all countries, we excluded international migrants who arrived after age 15.

Because no information on international migration was available for Hungary and the Netherlands, any migrants are included in the data for these countries. In Italy, in contrast, all migrants are excluded because there is no information on age at immigration.

Table A: Size of study populations for life tables, by country

|  |  |  |  | Ages of respondents |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\underline{\text { men }}$ | $\underline{\text { women }}$ | $\underline{\text { mothers }}$ | $\underline{\text { children }}$ | $\underline{\text { men }}$ | $\underline{\text { women }}$ |
| Austria | 1754 | 2583 | 1473 | 2871 | $18-45$ | $18-45$ |
| Belgium | 1429 | 1619 | 1149 | 2339 | $18-55$ | $18-54$ |
| Bulgaria | 4002 | 5065 | 3688 | 6395 | $17-55$ | $18-55$ |
| Czech R. | 3041 | 3090 | 1942 | 3559 | $17-55$ | $17-55$ |
| Estonia | 1735 | 2770 | 2166 | 4374 | $20-55$ | $20-55$ |
| France | 2546 | 3515 | 2275 | 4728 | $17-55$ | $17-55$ |
| Georgia | 3200 | 3713 | 2727 | 5800 | $18-55$ | $17-55$ |
| Germany (NEPS) | 3873 | 4071 | 2963 | 5872 | $21-55$ | $22-55$ |
| Hungary | 3670 | 4174 | 2980 | 5912 | $20-55$ | $20-55$ |
| Italy | -- | 12011 | 7090 | 13370 | -- | $18-55$ |
| Lithuania | 3227 | 3060 | 2072 | 3581 | $17-55$ | $17-55$ |
| Netherlands (FFS) | 3024 | 3476 | 2325 | 4897 | $18-55$ | $18-55$ |
| Norway | 4389 | 4529 | 3081 | 6754 | $18-55$ | $18-55$ |
| Poland | 4983 | 6287 | 4548 | 9273 | $18-55$ | $18-55$ |
| Romania | 3765 | 3444 | 2710 | 5154 | $18-55$ | $18-55$ |
| Russia | 2807 | 4204 | 3379 | 5662 | $17-55$ | $17-55$ |
| Spain (SFS) | -- | 5174 | 2877 | 5427 | -- | $14-55$ |
| Sweden | 2568 | 2779 | 1718 | 3649 | $17-55$ | $17-55$ |
| USA (NSFG) | 5302 | 6405 | 3269 | 6823 | $14-45$ | $14-45$ |

Even the data we include are not, of course, perfect. GGP surveys in the Czech Republic, Belgium, Russia, and the Netherlands are based on less than $50 \%$ participation. Declining response rates is a cause for concern for sample surveys in all countries considered. In addition, many histories are missing information that could not be imputed. Table B shows that in most countries, missing information produced a reduction in sample sizes of five percent or less. A very large fraction of respondents with unions in the Belgian GGS were excluded because no information was provided about whether they
had married or not. In Hungary and the Czech Republic, information is missing on year of union formation for relatively large proportions of respondents; patterns of union formation may thus be biased downwards for these countries. The Spanish Fertility Survey also includes a relatively high number of spells for which data could not be imputed. Georgia includes only data on registered marriages. In Georgia a non-negligible fraction of marriages are religious ones and not always registered with the authorities. This practice has gained in prevalence in recent years, for which we estimate our synthetic cohorts (Badurashvili et al., 2008). Many of unions that appear as cohabiting unions are thus actually marriages. Many other cohabiting unions may be de facto marriages as well to a much larger extent than what is the case in other countries. The same holds for Bulgaria, where at least ethnic minority people are less inclined than others to register their marriage with the authorities (Kostova 2008; Hoem and Kostova 2008). Even the majority population may show patterns where cohabiting couples behave as married people do. Cohabiting unions in Spain also show patterns that are surprisingly marriage like, with low levels of union dissolution (see similar findings in EspingAndersen et al., 2013).

Our life table analyses are based on periods of exposure and transitions occurring during the six years prior to each survey. Biographical reports are more accurate for recent events and the logic of our life-table analysis is to capture a current view of population processes that occur over two decades of an individual's life. Table C lists the study periods for which exposures and events are observed in each country, i.e., to which the synthetic cohort estimates apply.

| Table C: Study period / synthetic cohorts for life tables |  |
| :--- | :--- |
| Country | Study period |
| Austria | $2003-2009$ |
| Belgium | $2003-2010$ |
| Bulgaria | $1999-2004$ |
| Czech R. | $2000-2005$ |
| Estonia | $1999-2005$ |
| France | $2000-2005$ |
| Georgia | $2001-2006$ |
| Germany (NEPS) | $2003^{*} / 2005-2011$ |
| Hungary | $1999-2005$ |
| Italy | $1998-2003$ |
| Lithuania | $2001-2006$ |
| Netherlands (FFS) | $1998-2003$ |
| Norway | $2002-2008$ |
| Poland | $2005-2011$ |
| Romania | $2000-2005$ |
| Russia | $1999-2004$ |
| Spain (SFS) | $2001-2006$ |
| Sweden | $2007-2013$ |
| USA (NSFG) | $2001-2008$ |

*For tables on union formation the German study covers 9 years prior to survey

Some additional variations across surveys may affect our estimates. In Norway, we excluded respondents who had been widowed before age 50 because the date of partner's death was not reported. In the U.S., partner death was not recorded at all. In Germany, the Netherlands and Norway, respondents were not asked about the possible death of a child. Thus, all children reported are assumed to have survived to a parental separation, marriage, etc., up to age 15. In Sweden and the Netherlands, no information was available on when a child no longer resided with the mother, so it is assumed that children no longer living with the mother left home after age 15 (or an event of parental separation). Adopted children were not included in analyses of children's family events,
except in Sweden and Italy where no information is available on whether a child was adopted. In France, registered partnerships (PACs) are treated as marriages. In the Netherlands, the survey does not distinguish married from registered couples. Our estimates are based on weighted data only for the U.S. because minority groups were over-sampled and have very different family patterns to the majority.

## METHODS

Life-table estimates (Hoem 2001; 2011) are based on age- or duration-specific annual transitions over the period observed (Table C). Adult life courses are observed for the study of family formation from age 15 to event occurrence or age 50 (age 40 for some surveys) if an event of interest does not occur. When the event is contingent on an earlier event (e.g., separation or marriage within a cohabiting union), the window of observation is up to 15 years. Unions cease to be observed when a partner is known to have died. Children's life courses are observed from birth to age 15 if the event of interest does not occur. The event of leaving a parental union includes parental separation, moving away from both parents as well as the death of the father. Observations are otherwise censored when the child is known to have died or lived separately from the mother prior to age 15 ; such occurrences are quite rare. All durations are based on exact months.

Some events are competing, i.e., if one occurs the other cannot. Unions may be formed by cohabitation or marriage. Cohabitation may end by marriage or separation. In such cases we use single-decrement life tables, censoring at the occurrence of the competing event, and also double-increment life-tables where the same population is included in the risk set for each event. This means that the sum of the probabilities for the
competing events is the same as the probability for either event having occurred (Hoem 2011).

## ILLUSTRATIVE RESULTS

Appendix Tables 1-45 provide the complete life-table estimates for each transition or state over the entire age or duration range for each of the 19 countries. Andersson and Philipov (2002) provide further discussion of the logics behind these measures. Here we confine ourselves to present a few cross-national comparisons of selected indicators for adults, couples and children. These summary indicators are not necessarily presented in the order of the appendix tables; we chose to keep the appendix tables in the same order as Andersson and Philipov (2002) in order to facilitate comparisons across time.

Table D describes the transition to adulthood across countries. Cell entries are the median ages at leaving the parental home (Appendix Tables $1 \mathrm{a} / \mathrm{b}$ ), first union formation (Appendix Tables $6 \mathrm{a} / \mathrm{b}$ ), first marriage (Appendix Tables 7a/b), and first birth (Appendix Tables $8 \mathrm{a} / \mathrm{b}$ ): These are the ages when at least $50 \%$ of men and women have experienced the event of interest. Note that estimates for first marriage are independent of any cohabitation. Appendix Tables $2 \mathrm{a} / \mathrm{b}, 3 \mathrm{a} / \mathrm{b}, 4 \mathrm{a} / \mathrm{b}$ and $5 \mathrm{a} / \mathrm{b}$ provide estimates for first cohabitation and first marriage based on single-decrements (censoring for the other event) or double-decrements (competing risk) designs. As noted by "NA", the Spanish and Italian surveys did not include men, and questions on leaving home were not asked in the U.S. or Hungarian surveys.

Table D: Median Ages,
Transitions to Adulthood

|  | Men |  |  |  | Women |  |  |  |

| Italy | N.A. | N.A. | N.A. | N.A. | 28 | 30 | 31 | 33 |
| Austria | 24 | 26 | 35 | 34 | 21 | 24 | 33 | 30 |
| Netherlands | 24 | 26 | 32 | 33 | 21 | 23 | 29 | 30 |
| Belgium | 25 | 27 | 37 | 32 | 24 | 24 | 32 | 28 |
| Estonia | 25 | 25 | -- | 31 | 21 | 22 | 36 | 27 |
| Lithuania | 21 | 24 | 29 | 29 | 21 | 23 | 27 | 27 |
| Poland | 25 | 26 | 29 | 30 | 23 | 24 | 27 | 27 |
| Czech Republic | 24 | 28 | 37 | 36 | 23 | 25 | 29 | 28 |
| Hungary | N.A. | 29 | 35 | 34 | N.A. | 25 | 32 | 30 |
| Russian Federation | 21 | 24 | 27 | 28 | 20 | 21 | 24 | 24 |
| Romania | 26 | 28 | 30 | 31 | 23 | 24 | 25 | 26 |
| Bulgaria | 24 | 29 | 42 | 31 | 22 | 25 | 30 | 26 |
| Georgia | 29 | 29 | 40 | 30 | 24 | 25 | 37 | 26 |

The transition to adulthood varies quite dramatically across countries. Median ages at home-leaving range from 20 (Norway) to 29 (Georgia) for men, from 20 (Scandinavia, Germany, France and the Russian Federation) to 28 (Italy) for women. First union formation occurs later, with median ages 24 to 29 for men and 21 (Russia) to 30 (Italy) for women. In all countries, the age at which $50 \%$ of men and women have become a parent is higher than the corresponding age for first union formation: 28 (Russia) to 36 (Germany, Czech Republic) for men, 24 (Russia) to 33 (Italy) for women. Median age at first marriage is close to that for parenthood in several countries, but much
higher in countries where cohabitation is most common and a high proportion of births occur to cohabiting couples (see Table E below). The range is from 27 (Russia) to above 50 (in Estonia) for men, 24 (Russia) to 38 (Norway) for women. From these tables we note that Russia stands out as a country with very early family formation; Italy is an outlier with relatively late entry into adulthood (observed for women only). The complete life table estimates also provide information on the attainment of the combined statuses of partnership (any, none, marriage) and parenthood (parenthood in general, first birth).

An overview of union stability is shown in Table E. Estimates are based on a synthetic cohort of unions, observed at varying durations in the six years prior to interview. In this table, we do not distinguish between male and female respondents; all unions reported by men or women are included. (For Spain and Italy, where men were not interviewed, estimates are based on women's reports.) The table has been sorted so that countries appear in order of increasing levels of overall union instability; Georgia has the most stable, the U.S. the least stable co-residential unions.

The first column presents the proportion of cohabiting couples who marry within ten years of union formation. The estimates are based on a competing risk model of marriage (Appendix Table 21) and separation (Appendix Table 22) rather than a singledecrement model in which observations are censored at separation (Appendix Table 19). Least likely to marry within ten years are cohabiters in Sweden and Norway (one third of couples). Half or more of cohabiting couples are predicted to marry in Bulgaria, Czech Republic, Germany, the Netherlands, Poland, Romania and the Russian Federation.

Table E: Partnership Dynamics

|  | Cohabiters <br> married in 10 <br> years* | Separated within 10 years <br> Anions | Cohabiting** | Married** | Ratio C/M |
| :--- | :---: | :---: | :---: | :---: | ---: |
| Georgia | 47 | 7 | 7 | 6 | 1.17 |
| Spain | 45 | 12 | 17 | 8 | 2.13 |
| Romania | 58 | 13 | 20 | 8 | 2.50 |
| Bulgaria | 56 | 14 | 15 | 10 | 1.50 |
| Italy | 49 | 19 | 41 | 10 | 4.10 |
| Poland | 63 | 24 | 34 | 11 | 3.09 |
| Netherlands | 57 | 27 | 30 | 11 | 2.73 |
| Lithuania | 47 | 28 | 38 | 14 | 2.71 |
| Czech Republic | 50 | 31 | 36 | 19 | 1.89 |
| Belgium | 43 | 34 | 39 | -- |  |
| Estonia | 36 | 34 | 35 | 33 | 1.06 |
| Hungary | 39 | 34 | 46 | 13 | 3.54 |
| Germany | 51 | 38 | 40 | 17 | 2.35 |
| Russian Federation | 51 | 40 | 48 | 24 | 2.00 |
| Norway | 34 | 41 | 44 | 13 | 3.38 |
| Sweden | 33 | 46 | 47 | 20 | 2.35 |
| Austria | 42 | 46 | 48 | 16 | 3.00 |
| France | 39 | 49 | 51 | 20 | 2.55 |
| USA | 47 | 56 | 62 | 32 | 1.94 |

[^0]In the second column, we present the proportion of couples who separate within ten years of union formation (Appendix Table 26). The next two columns present estimates for unions that began as cohabitation (Appendix Table 24) and those that began as marriage (Appendix Table 25). Cohabiting couples who marry within the ten-year follow-up remain in the risk set for separation of cohabiters. For Belgium, the number of direct marriages during the observation window was too small for reliable life-table estimates of separation. The sample size was restricted due to a low survey response rate and a high proportion of missing data on marriage.

Dramatic differences in union stability are found, ranging from only $7 \%$ of all Georgian couples to $56 \%$ of U.S. couples separating within ten years of union formation. Much of the difference is accounted for by differential rates of separation among those who cohabited at the start of the union. In all countries, the likelihood of separation is greater for unions beginning with cohabitation than for those beginning with marriage. The complete life table estimates also provide information on the stability of childless couples (Appendix Table 18) and parental unions (Appendix Table 28).

Table F shows key parameters for the family experiences of children, based on mothers' birth and union histories. The first three columns present the distribution of births in marriage, cohabitation or to lone mothers (Appendix Table 30). Lone motherhood is rare in all countries, but notably higher in the U.S. (15\%) and the Russian Federation and Czech Republic (13\%). Births to cohabiting women comprise a third or more of all births in Sweden, Norway, France, Austria, Belgium, and Estonia. Marital births are overwhelmingly in the majority in Germany, the Netherlands, and the southern and majority of eastern European countries.

In the fourth column is the estimated percentage of children born to cohabiting parents whose parents marry by the child's sixth birthday (Appendix Table 40). These estimates are based on the synthetic cohorts of children observed during the six years prior to the survey, where parental separation is a competing risk. In no country does marriage occur within six years for more than $50 \%$ of children. Marriage is most common among cohabiting parents in Germany, Austria, and Poland, and quite unusual in Lithuania, Bulgaria and Georgia (where many cohabiting unions are de facto marriages).

Table F: Children's Family Experiences

|  | Mother's union at birth |  |  | Cohabiting | Parents separated by age 15* |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | No union | Cohabiting | Married | parents married by age 6 | Total | Cohabiting | Married |

* Children born in union, union status at childbirth

Columns 5-7 show the percent of children whose parents separate by their 15 th birthday. Column 5 is based on all children born in a union, either cohabitation or marriage (Appendix Table 33). Column 6 presents parallel estimates for children born to cohabiting parents. The child remains in the cohabiting risk pool even if the parents marry at some point during the 15 years of observation (Appendix Table 34). Column 7 presents estimates of parental separation for children born in marriage (Appendix Table 35).

The most stable parental couples are found in southern Europe, the Netherlands, Romania, Bulgaria and Georgia. Children are most likely to experience parental
separation in the USA (44\%) and the Russian Federation (42\%). In France, Estonia, Lithuania, and the Czech Republic, the chances of parental separation are more than one third. In every country, the chances of parental separation are greater for children born in cohabitation versus marriage. The differentials range from about $50 \%$ higher to more than four times as high.

Table F continued: Children's Family Experiences

|  | Stepfamily within 6 years |  |
| :--- | :---: | :---: |
|  | No union at birth | Separated parents |
| Sweden | -- | 40 |
| Norway | 55 | 41 |
| Germany | 54 | 34 |
| France | 34 | 36 |
| USA | 69 | 65 |
| Spain | 50 | 39 |
| Italy | 61 | 14 |
| Austria | 40 | 41 |
| Netherlands | 53 | 47 |
| Belgium | 44 | 60 |
| Estonia | 39 | 55 |
| Lithuania | 42 | 29 |
| Poland | 39 | 32 |
| Czech Republic | 37 | 35 |
| Hungary | 49 | 36 |
| Russian Federation | 35 | 37 |
| Romania | 25 | 30 |
| Bulgaria | 26 | 21 |
| Georgia | 45 | 14 |

The last two columns present a further step toward complex family lives for children, i.e., the acquisition of a step-parent. The second to last column presents estimates for children born to a lone mother (Appendix Table 36). Lone mothers' repartnering is a large majority experience in the U.S. and Italy. In all countries but

Bulgaria and Romania, stepfathers are acquired by more than one third of these children before their sixth birthday. In some cases, the mother may "re-partner" with the child's father, but we are not able to determine that from the GGP data. In many countries, the chances of acquiring a stepfather are somewhat lower after the child's co-resident parents separate (Appendix Table 43) than if the mother was not partnered at birth. But in many other countries, the difference is minimal or even reversed. For lone mothers, the child's young age may not pose as much of a barrier to step-fathering as do the older children of separated mothers. On the other hand, women who have children without a partner may be selected in two ways - they have chosen motherhood without partnership or they experience other disadvantages that make them less attractive on the partnering market.

Finally, we present Tables $G$ and $H$ (Appendix Tables 29a/b and 45) with descriptive summaries of the observed spells of men, women, and children in different family states during the six-year periods we cover. These summaries are simple statistics weighted for age; they are not based on any type of increment-decrement life-table analysis. Table G presents the percentage distribution of years between 15 and 50 that adults spend in the parental home, single without children (including years before any union formation and after the end of any childless union), cohabiting without children, married without children, cohabiting parent, married parent and single parent (including years before any union formation and years after separation from a child's other parent). Because Hungary and the U.S. did not collect information on home-leaving, years that would otherwise be counted as in the parental home are included in the time single without children. In this version of the table, we have sorted the countries according the
fraction of adults in the state as "married parent", with the lowest levels observed for Sweden and the highest for Romania.

Table G: Percentage of Time Ages 15-50

|  | Men |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Georgia | 23 | 8 | 2 | 2 | 8 | 49 | 8 |
| Bulgaria | 19 | 8 | 3 | 3 | 5 | 55 | 8 |
| Romania | 20 | 5 | 2 | 8 | 3 | 55 | 7 |

In every country, men and women spend on average as much or more time as a married parent than in any other family status. The range is from $24 \%$ to $47 \%$ for men and $28 \%$ to $55 \%$ for women. In both cases, Swedish adults spend least time and Romanian adults most time as married parents. Up to $14 \%$ of men's years and $17 \%$ of women's years are spent in cohabiting parenthood (Sweden, Estonia), but in most countries the proportions are under $10 \%$.

The second largest block of time between 15 and 50 is spent in the parental home. Swedish and Norwegian men spend the least amount of time in the parental home (about
$15 \%$ ), Polish and Czech men about twice as much. Norwegian women also spend the least time in the parental home ( $12 \%$ ) while nest-leaving of Spanish and Italian women occur very late; about one third of their time between age 15 and 50 is spent in the parental home. If we had data for Spanish and Italian men, the same would likely be true for them.

The fact that only small amounts of time are spent in childless marital or cohabiting unions arises from the fact that such unions quickly produce children and/or are dissolved. Where cohabitation is common, however, more time is spent in cohabitation than in marriage before children are born. The vast majority of time spent in single parenthood arises from time after separation from a child's other parent. Years in single parenthood are a function not only of the proportion of parents who separate but also the proportion who re-partner. Because fathers are more likely to re-partner than mothers, it is not surprising that the average man will spend less time in single parenthood than the average woman. The differences are especially pronounced in several eastern European countries.

Table H traces the amount of time children spend in different family arrangements. The table is sorted by the fraction of childhood time assigned to a family with two married parents. In every country, most time is spent living with the child's two parents, from a low of $66 \%$ in the U.S. to a high of $94 \%$ in Italy. In countries where cohabitation is a common context for parenthood (with Sweden and Estonia in the lead), a substantial proportion of the time is spent with cohabiting rather than married parents. The remaining window is more commonly filled by living with a single mother than by living in a stepfamily. Around a fifth of childhood time in the U.S., Russia, Lithuania and
the Czech Republic is with a lone mother, including lone mothers at birth and lone mothers after union dissolution.

Table H: Percentage of Time from Birth to Age 15

|  | Lone <br> mother | Cohab <br> parents | Married <br> parents | Separated <br> mother |  <br> stepfather |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Estonia | 5 | 22 | 53 | 11 | 9 |

| Spain | 2 | 5 | 87 | 3 | 1 |
| Italy | 1 | 2 | 92 | 4 | 1 |

## DISCUSSION

Our presentation provides new evidence of the degree of variation in family dynamics across contexts in Europe and between Europe and the U.S. Many of the patterns that arise appear similar to those observed some two decades ago based on data from the Fertility and Family Surveys. For example, family formation occurs relative late in Southern Europe and once families are formed they are more stable here than in most
other contexts. The role of non-marital cohabitation is very strong in Sweden and the U.S. once again stands out as a country with much more unstable families than anywhere in Europe. As compared to the summary by Andersson and Philipov (2002), many more countries in eastern Europe are represented in the Generations and Gender Programme. For post-communist countries covered in both studies we may note a shift in patterns towards later family formation and more family instability. Russia is a particularly interesting newcomer to this line of research: it is characterized by very early family formation and high levels of family instability.

Sample surveys are increasingly confronted with problems of non-response; in some cases respondent reports on family-life events may be inaccurate (Kreyenfeld and Bastin 2015). With this background we feel reassured by the fact that the vast amount of data we have processed produce patterns that appear so stable and systematic when compared to other sources of related information. During our work with these data we have relied on comparisons with the previous study by Andersson and Philipov and available statistics from many of the countries considered. In some cases, it is possible to validate survey data by comparisons to similar information from population registers. For Norway and Sweden we were able to compare some life-table estimates from the survey data to estimates from population registers. Because cohabitation is not a registered event, comparisons were possible only for events related to childbearing, marriage and divorce. We found few discrepancies, except for divorce where the survey-based estimates were lower than those from registers (Dommermuth et al., 2015 and authors' own calculations based on Swedish register data). This holds only for the few years prior to the survey, on which we base our synthetic cohorts. An inspection of linked register
data for the Swedish survey respondents show that this is not due to the non-reporting of events, rather to the sample selection, i.e., those who recently divorced are less likely to participate in the survey.

If response rates continue to decline, researchers may increasingly need to turn to alternative sources of information, such as those of population registers. For Denmark, Finland and Iceland it is already possible to produce the information provided in this report based on such data. For most other countries, sample surveys will be needed also in future research on family dynamics. In the field of family demography, Europe still offers a most compelling case for comparative research; nowhere else does a set of related countries provide such variation both in terms of family dynamics and the many contextual factors that may help us understand different patterns in family behavior.

## THE DATABASE

Our database is presented in Appendix Tables 1-45, with contents as follows.
Tables 1-16: Single-sex tables of family formation of men and women

## Experience of nest-leaving

1- leaving the parental home

## Experience of union formation

2- first union, as a cohabitation (censoring at marriage)
3- first union, as a marriage (censoring at cohabitation)
4- first union, as a cohabitation (competing-risks model)
5- first union, as a marriage (competing-risks model)

6- first union, as a marriage or a cohabitation (4+5)
7- first marriage
Experience of becoming a parent
8- first child
Experience of the combination of being a parent and being in different union statuses

9- parent and in a union
10- parent and married
11- parent and not in a union (lone parent)
Experience of specific contexts of family-formation/childbearing events
12- marriage during a first union
13- first child during a first union
14- first child during any union
15- first child during any marriage
16 - first child when out of union
Tables 17-28: Pooled tables of union transformation and union disruption
Childless couples: Experience of childbearing or separation
17- first child of a childless couple
18- separated before a birth, childless couple
Consensual unions: Experience of marriage formation or separation
19- married before dissolution
20- separated before marriage
21- married (competing-risks model)

22- separated (competing-risks model)
23- no longer in a consensual union (21+22)

## Couples' experience of union disruption

24- separation for unions begun as a cohabitation
25- separation for unions begun as a marriage
26- separation for all unions
27- separation for all marriages
28- separation of parents in union (duration since union/parenthood)
Summary measure
29- percent of time spent in different family types (men, women)
Tables 30-45: Children's experience of family dynamics

## Family type at birth

30- percent of births by family type

## Experience of family disruption

31- ever out of union (all children)
32- ever out of marriage (all children)
33- out of union (children born in union)
34- out of union (children born in consensual union)
35- out of union (children born in marriage)
Experience of family formation
36- in union (children born to lone mother)
37- in marriage (children born to lone mother)
38- in marriage (children born to cohabiting mother)

39- in marriage (children born to non-married mother)

## Competing-risks model for children born in consensual union

40- in marriage
41- out of union
42- no longer in consensual-union family (40+41)

## Experience of family re-formation

43- again in union (after parental separation)
44- in marriage (after parental separation)

## Summary measure

45- percent of time spent in different family types

## ACKNOWLEDGEMENTS

This study uses data from the Generations and Gender Programme (GGP). The GGP is a Social Science Research Infrastructure run by institutes with traditions in academic and policy-related research on population and family change and on survey methodology (www.ggp-i.org). The Harmonized Histories data file was created by the Non-Marital Childbearing Network (www.nonmarital.org; see Perelli-Harris et al. 2010). It harmonizes childbearing and marital histories from 14 countries in the Generations and Gender Programme (GGP) with data from Spain (Spanish Fertility Survey), United Kingdom (British Household Panel Study) and United States (National Survey for Family Growth). We acknowledge everyone who helped collect, clean, and harmonize the Harmonized Histories data, especially Karolin Kubisch at the Max Planck Institute for Demographic Research (MPIDR). Support for production of CLiCR data files was
provided by the Stockholm Centre on Health of Societies in Transition (SCOHOST) at Södertörn University. The study also uses data from the National Educational Panel Study: Starting Cohort 6 - Adults (doi:10.5157/NEPS:SC6:1.0.0). The NEPS data collection is part of the Framework Programme for the Promotion of Empirical Educational Research, funded by the German Federal Ministry of Education and Research.

We acknowledge financial support from the Swedish Research Council (Vetenskapsrådet) via the Linnaeus Center for Social Policy and Family Dynamics in Europe (SPaDE), grant registration number 349-2007-8701, and project grant 421-20141668 (Cohabitation and Family Complexity). Finally, we are grateful for advice and input on various aspects of our life table production from Irina Badurashvili, Eva Beaujouan, Sunnee Billingsley, Teresa Castro Martín, Johan Dahlberg, Anette Fasang, Paulina Galezewska, Jan Hoem, Romina Fraboni, Michaela Kreyenfeld, Dora Kostova, Karolin Kubisch, Lívia Murinkó, Eleonora Mussino, Brienna Perelli-Harris, Laurent Toulemon, and Kenneth Aarskaug Wiik.
